## Total Dust Attenuation

Four primary techniques:

- UV-to-NIR SED fitting (a known attenuation curve), constrain  $E(B-V)_{\rm star}$ ;
- Balmer decrement (an intrinsic ratio), e.g.,  $H\alpha/H\beta$ , constrain  $E(B-V)_{gas}$ ;
- Energy balance technique (statement), e.g., IRX- $\beta$  relation;
- Using luminous background source with a known intrinsic spectrum, e.g., MW extinction (Fitzpatrick et al., 2019).

Commonly used parameterization: the total-to-selective attenuation curve

$$k_{\lambda} = \frac{A_{\lambda}}{E(B-V)},$$

in which  $E(B-V) = A_B - A_V$ .

Dust

### Nebular-to-stellar Attenuation Ratio

Dust

### Two-component Dust Model

Charlot & Fall (2000)

$$\tau_{\lambda}^{\rm tot}(t) = \begin{cases} \tau_{\lambda}^{\rm BC} + \tau_{\lambda}^{\rm ISM} & t \leq t_{\rm BC}, \\ \tau_{\lambda}^{\rm ISM} & t > t_{\rm BC}, \end{cases}$$

$$\begin{split} \tau^{\rm BC/ISM}_{\lambda} &= \tau^{\rm BC/ISM}_V (\lambda/0.55 \mu {\rm m})^{-n}, \ n = 0.7, \\ t_{\rm BC} &= 10 \ {\rm Myr.} \\ {\rm da \ Cunha \ et \ al. \ (2008):} \ n_{\rm BC} &= 1.3, \\ n_{\rm ISM} &= 0.7. \\ {\rm Whitmore \ et \ al. \ (2014):} \ t_{\rm BC} &\lesssim 10 \ {\rm Myr \ in} \\ {\rm NGC \ 4038/39.} \\ {\rm Hollyhead \ et \ al. \ (2015):} \ t_{\rm BC} &< 4 \ {\rm Myr \ in} \\ {\rm M83.} \end{split}$$

Grasha et al. (2019):  $t_{BC} \lesssim 6$  Myr in M51.

### Two-component Dust Model

#### Wild et al. (2011)

- OB stars produce nebular emission lines
- dust opacity dominated by birth clouds
- predominantly (spherical) screen-like extinction
- T ~ TBirth Cloud

#### Intermediate-age stars

- mixed star-dust geometry
- attenuation primarily from diffuse ISM dust
- - τ ~ τ<sub>ISM</sub>

#### Old stars (also in bulge, not pictured)

- predominantly responsible for NIR light
- higher fraction in bulge and/or thick disk
- screen-like extinction (far-side)
- no attenuation (near-side)
- observe extinction law in NIR (τ ~ τ<sub>ext</sub>)

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

#### Diffuse ISM dust (with radial gradient)

- Diffuse dust
- Birth-cloud dust
- remains constant

-

 $\tau_{\lambda}^{\text{BC+ISM}}/\tau_{\lambda}^{\text{BC}}$  or  $E(B-V)_{\text{star}}/E(B-V)_{\text{gas}}$  may be not a constant for all type of galaxies (Wild et al., 2011; Zahid et al., 2017; Koyama et al., 2019; Qin et al., 2019; Lin & Kong, 2019).

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

3

## IRX- $\beta$ Relation

## Second Parameter

- Kong et al. (2004): stellar population parameters (SFH)
- Boquien et al. (2009) (H II regions): dust geometries and extinction curves
- Casey et al. (2014): SFR (or  $L_{IR}$ )
- Disadvantage:
  - Large uncertainties on IRX (Johnson et al., 2007)
  - Energy balance statement might be broken at scale  $\lesssim 1.5~{\rm kpc}$  (Williams et al., 2019)

Estimation of dust attenuation from the IRX- $\beta$  will give way to more robust techniques.

## Origin of Scatter

Popping et al. (2017): Starburst99+dust models

Narayanan et al. (2018): Cosmological zoom galaxy formation simulations

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

# UV-to-NIR SED fitting

- Age-dust degeneracy: poorly constrained dust attenuation from UV-NIR broadband SEDs
- Break the degeneracy: spectroscopic or FIR data
- Narrow spectroscopic features: stellar age and metallicity, e.g.,  $D_n(4000)$  and H $\delta$  (Kauffmann et al., 2003)
- FIR data: measurement of the total L<sub>IR</sub> (Noll et al., 2009a)

# Constraints on the Attenuation Curve

- Calzetti et al. (1994, 2000): assuming the same underlying stellar populations, compare galaxies with different  $\tau_B^l \rightarrow$  average attenuation curve for SB galaxies, shallower than the MW or LMC extinction curve, without 2175 Å bump
- Wild et al. (2011): pairs of galaxies with similar gas-phase metallicities, sSFRs, b/a but different  $\tau_B^l$
- Battisti et al. (2016); Battisti et al. (2017): local SFGs
- CIGALE fit for individual galaxies: Buat et al. (2018); Salim et al. (2018)
- High-z: Kriek & Conroy (2013); Reddy et al. (2015); Scoville et al. (2015); Zeimann et al. (2015); Cullen et al. (2018)

# 2175-Å dust feature

Expectation: normal SFGs should show evidence for the 2175 Å dust feature. Parameterize dust attenuation curve with a bump (NoII et al., 2009b):

$$\begin{split} A(\lambda) &= \frac{A_V}{4.05} (k_{\mathsf{Cal}}(\lambda) + D(\lambda)) \left(\frac{\lambda}{\lambda_V}\right)^{\delta} \\ D(\lambda) &= \frac{E_b (\lambda \Delta \lambda)^2}{(\lambda^2 - \lambda_0)^2 + (\lambda \Delta \lambda)^2}. \end{split}$$

# 2175-Å dust feature

Salim et al. (2018): local galaxies, a wide range of UV bump amplitudes with an average strength of 1/3 of the MW bump.

500

э

## Physical Dust Properties

Constraints on the  $M_{\rm dust}$  and  $T_{\rm dust}$  require data beyond the peak in the thermal dust emission spectrum at  $\sim 100~\mu{\rm m}.$ 

da Cunha et al. (2008) (MAGPHYS)

◆ロト ◆昼 ▶ ◆臣 ▶ ◆臣 ▶ ○臣 ○ のへで

## Physical Dust Properties

IR SED models:

#### Draine & Li (2007) (e.g., CIGALE)

- grain populations exposed to a variety of starlight intensities
- thermal emission and single photon heating of dust particles
- dust size distributions of MW  $(q_{\rm PAH})$  + emissivity for a dust mixture heated by U +  $dM_{\rm dust}/dU$
- free parameters:  $q_{\rm PAH}$ ,  $U_{\rm min}$ ,  $\gamma(U>U_{\rm min})$  (fixed  $\alpha=2$ ,  $U_{\rm max}=10^6$ , Draine et al. 2007)

With *Herschel* data: simplistic, modified blackbody dust models are no longer capable of providing adequate fits to the data.

## **Physical Dust Properties**

## Physical Dust Properties

IR SED models:

da Cunha et al. (2008) (MAGPHYS)

- an empirical spectrum for the PAH emission
- emission from stochastically heated grains
- warm and cold thermal dust

New update of MAGPHYS: add 2175 Å bump to attenuation curve (Battisti et al., 2019)

## Cosmic Evolution of IR SEDs

▲ロト ▲理ト ▲ヨト ▲ヨト 三ヨー 釣んぐ

## Constraints from SEDs

Problem: whether the IMF has had the same form over all of cosmic time and in all environments

- IMF-sensitive features: Nal doublet (0.82 μm), Call triplet (0.86 μm), FeH band head (0.99 μm)
- Extremely dwarf-rich IMFs are now routinely ruled out.
- More modest IMF variations appear to be supported by the data, at the level of a factor of 2–3 in M/L.

IMF

# Concluding Remarks

- Combining broadband data with moderate resolution spectra: IFU, narrow-band photometry, grism data (e.g., 3D-HST)
- Uncertainties in the SPS models are becoming a critical limiting factor to the interpretation of galaxy SEDs: include contributions from nebular emission and dust around AGB stars; FUV-FIR models, stellar evolution uncertainties
- A more sophisticated approach: derive the full posterior distributions via (e.g.,) MCMC techniques
- Understanding what is knowable from the modeling of galaxy SEDs
